

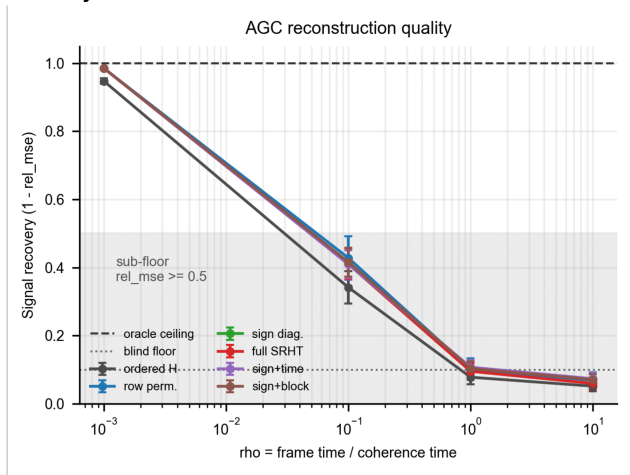

Figure 8. SRHT gains identifiability above the reconstruction floor

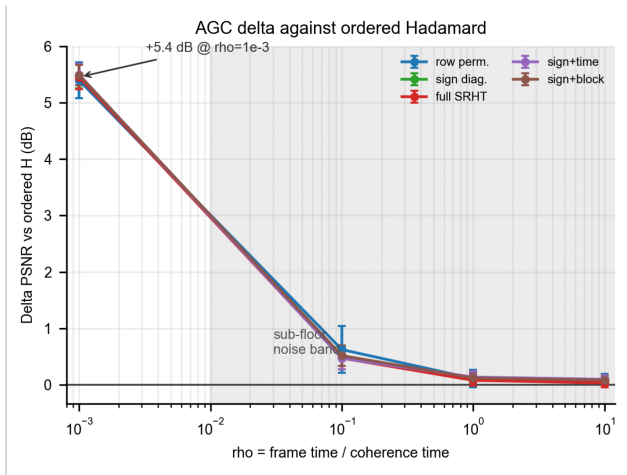

Random sign/permutation restores a stable coefficient anchor where gain is estimable; fast-drift deltas are floor coincidences.

Status: partial; fast ≥ 3 dB gate refuted, estimable-regime randomization result retained

A Quality and floor

B Delta vs ordered

M3 SRHT ablation under AGC over 10 objects x 5 seeds. Panel A reports signal recovery with an oracle ceiling and a $\text{rel_mse} \geq 0.5$ sub-floor band. Panel B reports delta PSNR relative to ordered Hadamard with data-detected sub-floor ρ cells shaded. SRHT/row permutation/diagonal signs give about +5.4 dB at $\rho=1e-3$, while $\rho=0.1$ is already transitional/sub-floor and $\rho \geq 1$ collapses every blind variant to the reconstruction floor; the residual moderate/fast-drift deltas are not interpreted as effects.
